

Evaluation Criteria - Experience Ecosystem

Purpose

This document is uploaded to the Experience Ecosystem agent's Knowledge Base. It contains the evaluation criteria used during the agent's internal self-review loop.

Layer A — Checklist Validation

Structural Completeness

- All 4 tables present: Users, Objects, Role-Object Interactions, Object-Object Interactions
- Comprehensive user role coverage: 7–15 roles for this system complexity
- Comprehensive object coverage: 15–30 objects for this system complexity
- Comprehensive role-object interactions: 40–70+ interactions
- Comprehensive object-object interactions: 20–40+ interactions

Relationship Integrity

- All user roles are distinct with real-world titles (no persona names)
- All objects are nouns — no tools, verbs, or features
- Actions are standardized single verbs across all relationships (Creates, Manages, Reviews, etc.)
- No User ↔ User links exist anywhere — users connect through objects only
- No Object ↔ Object links without action labels — every connection has a verb
- Every user role has at least one object interaction
- Every object is touched by at least one role or object

Traceability

- If UX Requirements available, user types are consistent (internal traceability)
- If UX Requirements available, scope activities correspond to objects (internal traceability)
- If Research Intelligence available, user ecosystem data enriches role identification

Visual Artifact Specific

- Output maps cleanly to the HTML template {{variable}} fields
- User roles and objects structured for node-based visual rendering
- Relationship data structured for connection rendering
- Summary counts (users, objects, interactions) surfaced for header display

Format & Presentation

- Relationships reflect real system behavior, not aspirational behavior
- No additional commentary before or after the tables
- Action verbs are standardized single words, not task-specific phrases

Layer B — Semantic Validation

Decision Advancement

Does the ecosystem map reveal the full system of relationships? Could a designer understand

how all parts of the system connect by reading this map alone?

Internal Coherence

Are all tables consistent? Every user in Table 1 should appear in Table 3. Every object in Table

2 should appear in Table 3 or Table 4. No orphan entries.

Actionability

Could a UX team use this map to identify handoff points, dependency gaps, and system boundaries without additional clarification
