

Wireframes — Agent KB

Evaluation Criteria

Purpose

This document is uploaded to the Wireframes agent's Knowledge Base. It contains the evaluation criteria used during the agent's internal self-review loop.

Layer A — Checklist Validation

Screen Prompt Quality

- Each screen prompt is 200–500 words
- Written in natural language as a product description — not specification notation
- Uses realistic sample data woven into the description (not a separate data block)
- Every button has its exact label
- Every table describes column names and 3–5 sample rows with actual values
- Every status/badge has its exact text
- Disabled states described with their condition

Product Description Style (Not Layout Spec)

- No hex colors, font sizes, font weights, or layout percentages
- No ALL-CAPS section headers or specification syntax
- No design system tokens, component specs, or pattern names
- Prompts read like a product manager describing what the screen does
- Content describes WHAT the product does, not HOW it looks

Screen Kit Completeness

- Product Brief present with: product name, domain, platform, user, style reference, navigation, flow summary
- All screens from the finalized workflow have prompts
- Connection Guide present mapping: screen → action → destination
- Conditional navigation clearly documented

Flow Continuity

- Each screen prompt references the previous screen context (where the user came from)
- Navigation items are consistent across all screen prompts
- Primary actions clearly state what happens next and which screen it leads to

Visual Artifact Specific

- Output maps cleanly to the HTML template {{variable}} fields
- Screen prompts render as individual cards in sequence
- Connection guide renders as a navigation map
- Product brief renders as a header summary

Format & Presentation

- No additional commentary outside the screen kit structure
- Screen prompts are self-contained — each can be copied independently into a prototyping tool

Layer B — Semantic Validation

Decision Advancement

Does each screen prompt contain enough information for an AI prototyping tool to generate a high-quality screen? Would the generated prototype be recognizable as the intended product?

Internal Coherence

Are all screen prompts consistent in navigation, terminology, and data? Does the user's journey make logical sense from Screen 1 through the final screen?

Actionability

Could a designer copy any single screen prompt into Figma Make / Stitch / V0 and get a usable prototype screen without additional context?
